Agenda

- **Functional Interfaces in Java 8**
- Types of Interfaces
- Primitive Versions of Functional Interfaces
- Binary Versions of Functional Interfaces
- BinaryOperator

Functional Interfaces in Java 8 (1/3)

■ What Is Functional Programming in Java?

- Functional programming emphasizes on declarative aspects of programming where business logic is composed of pure functions, an idea that somewhat contrasts the essence of object-oriented methodology

Ref: <http://prikid.biz/what-is-a-template-in-java.html>

Functional Interfaces in Java 8 (2/3)

- The **java.util.function** has numerous built-in functional interfaces.
- **Built-in Functional Interfaces:**
 - Declares a single abstract method
 - Can have any number of default or static methods
 - Are useful for creating lambda expressions
- Figure shows some of the key functional interfaces from the **java.util.function** package and their abstract method.

Functional Interfaces	Method
Predicate<T>	Boolean test (T t)
Consumer<T>	void accept (T T)
Function<T, R>	R apply (T t)
Supplier<T>	T get()

Functional Interfaces in Java 8 (3/3)

- Table discuss four important built-in interfaces in the **java.util.function** package: Predicate, Consumer, Function, and Supplier.

Functional Interfaces	Description	Common Use
Predicate<T>	<ul style="list-style-type: none">Checks a condition and returns a boolean value as result	<ul style="list-style-type: none">In filter() method in java.util.stream. Stream which is used to remove elements in the stream that don't match the given condition (i.e., predicate) as argument.
Consumer<T>	<ul style="list-style-type: none">Operation that takes an argument but returns nothing	<ul style="list-style-type: none">In forEach() method in collections and in java.util.stream. This method is used for traversing all the elements in the collection or stream.
Function<T>	<ul style="list-style-type: none">Functions that take an argument and return a result	<ul style="list-style-type: none">In map() method in java.util.stream. Stream to transform or operate on the passed value and return a result.
Supplier<T>	<ul style="list-style-type: none">Operation that returns a value to the caller	<ul style="list-style-type: none">In generate() method in java.util.stream. Stream to create an infinite stream of elements.

Agenda

- Functional Interfaces in Java 8
- **Types of Interfaces**
- Primitive Versions of Functional Interfaces
- Binary Versions of Functional Interfaces
- BinaryOperator

Predicate Interface

- We often need to use functions that check a condition and return a boolean value.
- In this case, we can use the **Predicate** functional interface.
- Figure shows the abstract named **test()** that takes an argument and returns **true** or **false**.

```
@FunctionalInterface
public interface Predicate<T> {
    boolean test(T t);
    // other methods elided
}
```

- The **Predicate** functional interface also defines default methods namely, **and()** and **or()** that takes a **Predicate** and returns a **Predicate**.
- It also has a **negate()** method whose behavior is similar to the **!** Operator.

Consumer Interface (1/2)

- There are many methods that take one argument, perform some operations based on the argument but do not return anything to their callers—they are **consumer** methods.
- Figure shows the declaration of abstract method named **accept()** defined in the **Consumer** interface.

```
@FunctionalInterface
public interface Consumer<T> {
    void accept(T t);
    // the default andThen method elided
}
```

- The **accept()** method “consumes” an object and returns nothing (**void**).
- The following code snippet demonstrates the use of the **Consumer** interface:

```
Consumer<String> printUpperCase = str -> System.out.println(str.toUpperCase());

printUpperCase.accept("hello");
// prints: HELLO
```

- In this code, the lambda expression takes the given string, converts to upper case, and prints it to the console. We are passing the actual argument “hello” to the **accept()** method.

Consumer Interface (2/2)

- Consumer interface also has a default method named **andThen()**; it allows chaining calls to **Consumer** objects.
- Consumer **andThen()** returns a composed Consumer that performs, in sequence, for the current operation followed by the after operation.
- The syntax of the andThen() method are as follows:

```
default Consumer<T> andThen(Consumer<? super T> after)
```

- Following code snippet shows the use of andThen():

```
Consumer<String> c = (x) -> System.out.println(x.toLowerCase());  
c.andThen(c).accept("java8");
```

//prints:

java8

java8

Function Interface

- The **Function** interface defines a single abstract method named **apply()** that takes an argument of generic type **T** and returns an object of generic type **R**.
- Figure shows the abstract method named **apply()** in the **Function** interface.

```
@FunctionalInterface
public interface Function<T, R> {
    R apply(T t);
    // other methods elided
}
```

- ```
Function<String, Integer> strLength = str -> str.length();
System.out.println(strLength.apply("supercalifragilisticexpialidocious"));
// prints: 34
```
- This code takes a string and returns its length, as a result of making the call to **apply()** method.
- Advantages of Function interface:
  - In all scenarios where an object of a particular type is the input, an operation is performed on it and object of another type is returned as output

# Function Interface: Helper Methods

- The Function interface contains the following default and static methods:

```
default <V> Function<T, V> andThen(Function<? super R,? extends V> after) default <V>
Function<V, R> compose(Function<? super V,? extends T> before) static <T> Function<T, T>
identity()
```

- **andThen()** creates a Function that calls the current function and specified function after to get the result.
- **compose()** creates a Function that calls the specified function then current function and returns the result.
- **identify()** creates a function that returns its argument.

# Function Interface: Specialization

- There are six specialization of the `Function<T, R>` interface:
  - `IntFunction<R>`
  - `LongFunction<R>`
  - `DoubleFunction<R>`
  - `ToIntFunction<T>`
  - `ToLongFunction<T>`
  - `ToDoubleFunction<T>`
- **`IntFunction<R>`**, **`LongFunction<R>`**, and **`DoubleFunction<R>`** take an int, a long, and a double as an argument, respectively, and their return value is in type R.
- **`ToIntFunction<T>`**, **`ToLongFunction<T>`**, and **`ToDoubleFunction<T>`** take an argument of type T and return an int, a long, and a double, respectively.

# Function Interface: IntFunction

- **IntFunction** represents a function that accepts an int-valued argument and produces a result.
- This is the int-consuming primitive specialization for Function.
- Following code snippet shows how to use IntFunction:

```
IntFunction<String> i = (x)->Integer.toString(x);

System.out.println(i.apply(3).length());
```

# Supplier Interface (1/2)

- There are method that does not take any input but returns some output, they are supplier methods.
- Figure shows the abstract method in the **Supplier** interface.

```
@FunctionalInterface
public interface Supplier<T> {
 T get();
 // no other methods in this interface
}
```

- Following code snippet returns a value without taking anything as input:

```
Supplier<String> currentDateTime = () -> LocalDateTime.now().toString();

System.out.println(currentDateTime.get());
```

- The lambda expression does not take any input but returns the current date/time as a **String** format.

## Supplier Interface (2/2)

- Following code snippet makes use of constructor references:

```
Supplier<String> newString = () -> new String();
System.out.println(newString.get());
```

- This lambda expression returns a new **String** object.

# Agenda

- Functional Interfaces in Java 8
- Types of Interfaces
- **Primitive Versions of Functional Interfaces**
- Binary Versions of Functional Interfaces
- BinaryOperator

# Primitive Versions of Functional Interfaces (1/6)

- The built-in interfaces **Predicate**, **Consumer**, **Function**, and **Supplier** operate on reference type objects.
- For primitive types there are specializations available for **int**, **long** and **double** types for these functional interfaces.
- For example,
  - Consider **Predicate** that operates on objects of type T, i.e., it is **Predicate<T>**.
  - The specializations for int, long, and double for Predicate are **IntPredicate**, **LongPredicate**, and **DoublePredicate** respectively.
- When you try to use primitive types with these functional interfaces, it results in implicit autoboxing and unboxing.
- For example, an **int** value gets converted to an **Integer** object and vice versa.

## Primitive Versions of Predicate Interface (2/6)

- Table shows the primitive versions of Predicate interface.

| Functional Interface | Abstract Method                                                            | Description                                                                                                                    |
|----------------------|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| IntPredicate         | <ul style="list-style-type: none"><li>boolean test(int value)</li></ul>    | <ul style="list-style-type: none"><li>Evaluates the condition passed as int and returns a boolean value as result</li></ul>    |
| LongPredicate        | <ul style="list-style-type: none"><li>boolean test(long value)</li></ul>   | <ul style="list-style-type: none"><li>Evaluates the condition passed as long and returns a boolean value as result</li></ul>   |
| DoublePredicate      | <ul style="list-style-type: none"><li>boolean test(double value)</li></ul> | <ul style="list-style-type: none"><li>Evaluates the condition passed as double and returns a boolean value as result</li></ul> |

# Primitive Versions of Function Interface (3/6)

- Table shows the primitive versions of Function interface.

| Functional Interface | Abstract Method                                                           | Description                                                                                                                |
|----------------------|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| IntFunction<R>       | <ul style="list-style-type: none"><li>R apply(int value)</li></ul>        | <ul style="list-style-type: none"><li>Operates on the passed int argument and returns value of generic type R</li></ul>    |
| LongFunction<R>      | <ul style="list-style-type: none"><li>R apply(long value)</li></ul>       | <ul style="list-style-type: none"><li>Operates on the passed long argument and returns value of generic type R</li></ul>   |
| DoubleFunction<R>    | <ul style="list-style-type: none"><li>R apply(double value)</li></ul>     | <ul style="list-style-type: none"><li>Operates on the passed double argument and returns value of generic type R</li></ul> |
| ToIntFunction<T>     | <ul style="list-style-type: none"><li>int applyAsInt(T value)</li></ul>   | <ul style="list-style-type: none"><li>Operates on the passed generic type argument T and returns an int value</li></ul>    |
| ToLongFunction<T>    | <ul style="list-style-type: none"><li>long applyAsLong(T value)</li></ul> | <ul style="list-style-type: none"><li>Operates on the passed generic type argument T and returns a long value</li></ul>    |

# Primitive Versions of Function Interface (4/6)

- Table shows the primitive versions of Function interface.

| Functional Interface | Abstract Method                                                                 | Description                                                                                                                |
|----------------------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| ToDoubleFunction<T>  | <ul style="list-style-type: none"><li>double applyAsDouble(T value)</li></ul>   | <ul style="list-style-type: none"><li>Operates on the passed generic type argument T and returns an double value</li></ul> |
| IntToLongFunction    | <ul style="list-style-type: none"><li>long applyAsLong(int value)</li></ul>     | <ul style="list-style-type: none"><li>Operates on the passed int type argument and returns a long value</li></ul>          |
| IntToDoubleFunction  | <ul style="list-style-type: none"><li>double applyAsDouble(int value)</li></ul> | <ul style="list-style-type: none"><li>Operates on the passed int type argument and returns a double value</li></ul>        |
| LongToIntFunction    | <ul style="list-style-type: none"><li>int applyAsInt(long value)</li></ul>      | <ul style="list-style-type: none"><li>Operates on the passed long type argument and returns an int value</li></ul>         |
| LongToDoubleFunction | <ul style="list-style-type: none"><li>double applyAsLong(long value)</li></ul>  | <ul style="list-style-type: none"><li>Operates on the passed long type argument and returns a doublevalue</li></ul>        |
| DoubleToIntFunction  | <ul style="list-style-type: none"><li>int applyAsInt(double value)</li></ul>    | <ul style="list-style-type: none"><li>Operates on the passed double type argument and returns an intvalue</li></ul>        |
| DoubleToLongFunction | <ul style="list-style-type: none"><li>long applyAsLong(double value)</li></ul>  | <ul style="list-style-type: none"><li>Operates on the passed double type argument and returns a longvalue</li></ul>        |

# Primitive Versions of Consumer Interface (5/6)

- Table shows the primitive versions of Consumer interface.

| Functional Interface | Abstract Method                                                                | Description                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| IntConsumer          | <ul style="list-style-type: none"><li>void accept(int value)</li></ul>         | <ul style="list-style-type: none"><li>Operates on the given int argument and returns nothing</li></ul>                                 |
| LongConsumer         | <ul style="list-style-type: none"><li>void accept(long value)</li></ul>        | <ul style="list-style-type: none"><li>Operates on the given long argument and returns nothing</li></ul>                                |
| DoubleConsumer       | <ul style="list-style-type: none"><li>void accept(double value)</li></ul>      | <ul style="list-style-type: none"><li>Operates on the given double argument and returns nothing</li></ul>                              |

# Agenda

- Functional Interfaces in Java 8
- Types of Interfaces
- Primitive Versions of Functional Interfaces
- **Binary Versions of Functional Interfaces**
- BinaryOperator

# Binary Versions of Functional Interfaces

- The functional interfaces namely, Predicate, Consumer, and Function have one abstract method in them.
- However, these interfaces also have binary versions.
- The prefix “Bi” indicates the version that takes “two” arguments.
- There are **BiFunction**, **BIPredicate**, **BiConsumer** for Function, Predicate and **BiConsumer** for Consumer that takes two arguments.

Since the abstract method in **Supplier** does not take any argument, there is no equivalent **BiSupplier** available.

- Table shows the binary versions of functional interfaces.

| Functional Interface | Abstract Method                                                          | Description                                                                                                                         |
|----------------------|--------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| BiPredicate<T, U>    | <ul style="list-style-type: none"><li>▪ boolean test(T t, U u)</li></ul> | <ul style="list-style-type: none"><li>▪ Checks if the arguments match the condition and returns a boolean value as result</li></ul> |
| BiConsumer<T, U>     | <ul style="list-style-type: none"><li>▪ void accept(T t, U u)</li></ul>  | <ul style="list-style-type: none"><li>▪ Operation that consumes two arguments but returns nothing</li></ul>                         |
| BiFunction<T, U, R>  | <ul style="list-style-type: none"><li>▪ R apply(T t, U u)</li></ul>      | <ul style="list-style-type: none"><li>▪ Function that takes two argument and returns a result</li></ul>                             |

# BiFunction and BiPredicate Interface

- Following code snippet demonstrates the use of BiFunction interface:

```
BiFunction<String, String, String> concatStr = (x, y) -> x + y;
System.out.println(concatStr.apply("hello ", "world"));
// prints: hello world
```

- Here, both the arguments are of same type, that is **String**. However, they can be of different types.
- Following code snippet demonstrates the use of **BiPredicate** interface:

```
BiPredicate<Integer, Integer> bi = (x, y) -> x > y;
System.out.println(bi.test(2, 3));
// prints: false
```

- **BiPredicate** represents a predicate which is a boolean-valued function of two arguments.

# BiConsumer andThen

- BiConsumer andThen returns a composed BiConsumer that performs, in sequence, this operation followed by the after operation.
- **Syntax:**

```
default BiConsumer<T,U> andThen(BiConsumer<? super T,? super U> after)
```

- Following code snippet shows how to use **andThen**:

```
BiConsumer<String, String> biConsumer = (x, y) ->
{
 System.out.println(x);
 System.out.println(y);
};
biConsumer.andThen(biConsumer).accept("Java 8", " Lambdas");
// prints: Java 8
 Lambdas
 Java 8
 Lambdas
```

# Agenda

- Functional Interfaces in Java 8
- Types of Interfaces
- Primitive Versions of Functional Interfaces
- Binary Versions of Functional Interfaces
- **BinaryOperator**

# BinaryOperator (1/2)

- **BinaryOperator** represents an operation upon two operands of the same type, producing a result of the same type.
- This is a specialization of **BiFunction** for the case where the operands and the result are all of the same type.
- This is a functional interface whose functional method is:
  - `BiFunction.apply(Object, Object)`
- Table shows the static methods of `BinaryOperator`.

| Method                                                                                               | Description                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>static &lt;T&gt; BinaryOperator &lt;T&gt; maxBy(Comparator&lt;? Super T&gt; comparator)</code> | <ul style="list-style-type: none"><li>▪ Returns a <code>BinaryOperator</code> which returns the greater of two elements according to the specified <code>Comparator</code>.</li></ul> |
| <code>static &lt;T&gt; BinaryOperator &lt;T&gt; minBy(Comparator&lt;? Super T&gt; comparator)</code> | <ul style="list-style-type: none"><li>▪ Returns a <code>BinaryOperator</code> which returns the lesser of two elements according to the specified <code>Comparator</code>.</li></ul>  |

## BinaryOperator (2/2)

- Following code snippet shows how to use BinaryOperator:

```
BinaryOperator<Integer> adder = (n1, n2) -> n1 + n2;
```

```
System.out.println(adder.apply(3, 4));
```

```
//prints: 7
```

- Following code snippet shows how to use **maxBy()** method:

```
BinaryOperator<Integer> bi = BinaryOperator.maxBy(Comparator.reverseOrder());
```

```
System.out.println(bi.apply(2, 3));
```

```
//prints: 2
```
